## Exercise Booklet 2: Mutual Exclusion

**Exercise 1.** Show that Attempt IV at solving the MEP, as seen in class and depicted below, does not enjoy freedom from starvation. Reminder: in order to do so you must exhibit a path in which one of the threads is trying to get into its CS but is never able to do so. Note that the path you have to exhibit is infinite; it suffices to present a prefix of it that is sufficiently descriptive.

```

1  boolean wantP = false;
2  boolean wantQ = false;

3  Thread.start { //P           4  Thread.start { //Q
4      while (true) {           5      while (true) {
5          // non-critical section 6          // non-critical section
6          wantP = true;         7          wantQ = true;
7          while wantQ {         8          while wantP {
8              wantP = false;    9              wantQ = false;
9              wantP = true;     10             wantQ = true;
10         }                    11         }
11         // CRITICAL SECTION  12         // CRITICAL SECTION
12         wantP = false;        13         wantQ = false;
13         // non-critical section 14         // non-critical section
14     }                        15     }
15 }                          16 }
```

**Exercise 2.** Consider the following proposal for solving the MEP problem for two threads, that uses the following functions and shared variables:

```

1  int current = 0, turns = 0;

1  def requestTurn() {          1  def freeTurn() {
2      turn = turns;            2      current = current + 1;
3      turns = turns + 1;      3      turns = turns - 1;
4      return turn;            4  }
5  }
```

We assume that each thread executes the following protocol:

```

1  while (true) {
2      // non-critical section
3      turn = requestTurn();
4      await (current==turn);
5      // critical section
6      freeTurn();
7      // non-critical section
8  }
```

1. Show that this proposal does not guarantee mutual exclusion.
2. Assume that both operations `requestTurn` and `freeTurn` are atomic.
  - (a) Show that this proposal still does not guarantee mutual exclusion
  - (b) Show that even if the operations are atomic, freedom from starvation fails.

**Exercise 3.** Consider the following extension of Peterson's algorithm for  $n$  processes ( $n > 2$ ) that uses the following shared variables:

```

1 def boolean flags = [false] * n; // initialize list with n copies of false
  and the following auxiliary function
1 def boolean flagsOr(id) {
2   result = false;
3   (0..n-1).each {
4     if (it != id)
5       result = result || flags[it];
6   }
7   return result;
8 }

```

Moreover, each thread is identified by the value of the local variable `threadId` (which takes values between 0 and  $n - 1$ ). Each thread uses the following protocol.

```

1   ...
2   // non-critical section
3   flags[threadId] = true;
4   while (FlagsOr(threadId));
5   // critical section
6   flags[threadId] = false;
7   // non-critical section
8   ...

```

1. Explain why this proposal does enjoys mutual exclusion. Hint: reason by contradiction.
2. Does it enjoy absence of livelock?

**Exercise 4.** Use a state diagram to show that Peterson's algorithm solves the MEP.

**Exercise 5.** Consider the simplified presentation of Bakery's Algorithm for two processes seen in class:

```

1  int np,nq =0;
2  thread P: {
3    while (true) {
4      // non-critical section
5      [np = nq + 1];
6      await nq==0 or np<=nq;
7      // CRITICAL SECTION
8      np = 0;
9      // non-critical section
10   }
11 }
2  thread Q: {
3    while (true) {
4      // non-critical section
5      [nq = np + 1];
6      await np==0 or nq<np;
7      // CRITICAL SECTION
8      nq = 0;
9      // non-critical section
10   }
11 }

```

Show that if we do not assume that assignment is atomic, then mutual exclusion is not guaranteed. For that, provide an offending path for the following program:

```

1  int np,nq =0;
2  thread P: {
3    while (true) {
4      // non-critical section
5      temp = nq;
6      np = temp + 1;
7      await nq==0 or np<=nq;
8      // CRITICAL SECTION
9      np = 0;
10     // non-critical section
11   }
12 }
2  thread Q: {
3    while (true) {
4      // non-critical section
5      temp = np;
6      nq = temp + 1;
7      await np==0 or nq<np;
8      // CRITICAL SECTION
9      nq = 0;
10     // non-critical section
11   }
12 }

```

**Exercise 6.** Given *Bakery's Algorithm*, show that the condition  $j < \text{threadId}$  in the second while is necessary. In other words, show that the algorithm that is obtained by removing this condition (depicted below) fails to solve the MEP. Indeed, show that it may livelock.

```
1 def choosing = [false] * N; // list of N false
2 def ticket = [0] * N // list of N 0
3
4 thread {
5   // non-critical section
6   choosing[threadId] = true;
7   ticket[threadId] = 1 + maximum(ticket);
8   choosing[threadId] = false;
9   (0..n-1).each {
10    await (!choosing[it]);
11    await (ticket[it] == 0 ||
12          (ticket[it] < ticket[threadId] ||
13           (ticket[it] == ticket[threadId]))
14          );
15  }
16  // critical section
17  ticket[threadId] = 0;
18  // non-critical section
19 }
```
